

Intro (1m 55s) - Kathy

As you all would know by now, we've been working on a one-click job application process using a chrome extension. Applying for jobs has required a full-time effort as job seekers need to go through a repetitive process of completing long application forms across multiple platforms and individual company websites. The majority of these applications require job seekers to re-enter the same personal details over and over again which can make this process feel super tedious.

So that's the quick recap, now I'll give a brief overview of the application structure for LinkedIn and Seek with the chrome extension.

[CANVA, IMPROV]

- Here we have two buttons integrated in the chrome extension: a review button and an apply button. These are the main buttons the user would interact with across multiple platforms. Lawrence will go further into the functionality a little later.
- So in the last demo, we completed easy apply in LinkedIn but then we found some bugs with resume uploads and some edge cases. We have now addressed these in sprint 3. (if they ask, edge cases were about early discarding an application, and just addressing that).
- The easy apply button displays a modal.
- Our challenge was to complete the apply button here which redirects to the company's website.
- This is also the same case in Seek as well, where we have a quick apply button that redirects us to the internal seek application.
- And an apply button which redirects to the company's website.

So thats it for the overview.

I'll hand it over to Lawrence to showcase the improvements with our chrome extension.

Easy apply for LinkedIn (1m 43s) → **LAWRENCE**

- progress tab
- review and apply button warnings

In our latest update to the Easy Apply feature on LinkedIn, we prioritized clear and intuitive user communication as a core focus. According to the client our approach stands out significantly due to our strong emphasis on user-focused design. Previously, users often expressed uncertainty about the outcomes of the extension. Recognizing this confusion, we've proactively introduced informative visual warnings directly linked to these critical actions.

Now, when users hover over the "Review" button, they see a clear indication that this step will halt at the final review page, providing them a final opportunity to review their information. Likewise, hovering over the "Apply" button explicitly informs them that this action will submit their application immediately.

We also revamped the progress ui, to display the steps being taken during the automation.

These improvements greatly enhance transparency and boost user confidence. Our users now feel included and informed at every step, confidently proceeding without uncertainty or guesswork. This deliberate user-centric design distinguishes our solution, setting a higher standard in usability and communication.

I'll hand it off to lachlan now to demo Normal apply.

Normal apply for LinkedIn

- Account creation for Workday (2min) → **LACHLAN**

- **Single Page Normal apply**

-

SAM: Normal apply single page (1m 49s) → **SAM**

we also have the extension working and autofilling where the job website takes us to the company's individual webform which we call normal apply. We've broken down our normal application process into two different processes handling two different types of forms. Single page forms and double paged forms. The reason we've broken them into two separate forms is because multipage forms require a different level of complexity where it needs user intervention. I will now showcase the single form process. I have prepared these two websites of single page format. So when the user clicks on apply here it will take them to another page where the extension will detect on the url if there are key words like job/apply, application and submitqqqq. When the extension detects that there are keywords in the url it will auto detect and answer fields using an api. As you can see this function handles open ended questions, drop downs, and uploads resume too.

Gobind: (2m38s)

Thank you Sam. . Many major job platforms use sophisticated security measures to prevent botting including Captcha challenges, Email verification, sms verification, etc. One company that does employ these tactics is amazon. Which is why for we're implemented a slightly different way to use our extension in sites like this.

So ive created a new amazon jobs account for this demo, and as you can see theres no information saved. If we open the extension, and you'll notice how it looks very differrent, and click autofill, it fills out this page. Then the user clicks next, and we can see the next page. Now some fields are unable to be autofilled as they require the user to do something very specific. for example, this date field requires a date to be clicked with cant be autofilled.

then we go to the final page that can be autofilled. many of amazons jobs follow this same format, which is why this is ideal for a quick and easy autofilling feature. after this page, everything else is manual, like the resume uploads, and legal agreements that should be properly read and understood before accepting.

Another site would be Google, and google requires you to upload a resume before you start applying, and they attempt to fill out the form based on the resume but it is quite innaccurate. So lets just autofill this page. you can see most elements are filled out, and even open ended questions are filled out using our custom API specifically for answering

job application questions. Ill pass it on to sam to show our efforts with dynamically clearing localStorage.

SAM (2m 04s)

So as per request from the previous demo, we've addressed the issue with clearing local storage where previously it was a manual clear but now we've automated it. So in [JobGen.AI](#), a user would fill in their personal information. Then when they use the chrome extension, the fields would populate with the same data from [JobGen.AI](#).

I'll show an example with a phone number change.

[SHOW LINKEDIN FIRST, THEN CHANGE NUMBER]

This confirms our ability to update user information on the JobGen.AI backend.

We have discovered a significant security vulnerability on the client side. Multiple users have the same JSON Web Token (JWT), and because of this, an unauthorised person with a shared token can access other people's information which is a huge security flaw. We will notify the client and address it in our report.

Easy apply for Seek (3m 28s) → **AQIL**

Thank you Sam, Throughout this project, our primary focus has been on perfecting our software for LinkedIn. Now that we've successfully implemented that automation, we used the skills and knowledge gained from building the LinkedIn integration and managing JobGen API calls to expand our functionalities to another major job board - Seek.com.

Seek presented unique challenges that LinkedIn didn't have:

1. Users can only store 10 resumes maximum in their profile
2. Every Seek application supports both resume AND cover letter uploads
3. Different form structures and automation requirements

Let me demonstrate how we've elegantly handled these challenges with complete end-to-end automation.

Demo flow -

Jobs page

Review

Show resume limit:

Our system detects the limit, shows a clear explanation to the user, automatically selects the oldest resume for deletion, and seamlessly uploads the new AI-generated resume

Note the cover letter notification

Unlike LinkedIn, every Seek application supports cover letters. Our system automatically generates and uploads a tailored cover letter for each position

Discuss the auto filling

Explain why there is a notification for cover letter and show that resume can already be viewed easily.

So, on this review page, the user has the control to change the autofilling the AI has completed, if they wish. If they want to view their resume, they can easily do so on this page by going [here]. Seek does not allow a user to view the cover letter however, therefore this cover letter notifications provides the user with transparency on what the AI has generated for their cover letter.

And thats it, the user can click submit and its all done with complete end-to-end automation for Seek

Ultimately, from the beginning of this project to the end, we quickly expanded from LinkedIn to Seek, and adapted to each platform's unique requirements while maintaining the same intelligent automation core. The system now works seamlessly across multiple job boards.

Conclusion

Alright, so today, we've showcased a comprehensive chrome extension that works seamlessly across multiple platforms - LinkedIn Easy Apply, LinkedIn Normal Apply, Workday, major tech companies like Google and Amazon, and now [Seek.com](https://www.seek.com.au), saving job seekers hours of repetitive form filling while maintaining user control and transparency.

ANSWERS

1. Can you elaborate on the process of uploading documents? How does the extension handle the tailored resume and cover letter from the backend?

GOBIND: When an application is initiated, the extension sends job data to our API. The API returns a tailored resume and cover letter. The extension then takes these documents and uploads them to the correct upload fields on the application form, so that the correct documents are submitted.

2. What happens if a form contains a new or unexpected field that the extension hasn't encountered before?

AQIL: Our solution is designed to be adaptable. While it has default strategies for common fields, it handles unexpected fields by either falls back to a default value or to the API for assistance so that the application doesn't get stuck and can be completed without manual intervention.

3. How much control does the user have in this chrome extension since this is a one-click process?

LACHLAN: To maintain user control, the application process includes a critical preview screen, this is shown in the review button. The review button is for those who are skeptical about the whole auto-submit so after the extension auto-fills the form, it would stop at the preview page for the user to edit their info. Else If the user trusts the auto-submit, they can click on the apply button instead, which would send off the application immediately after they click the button.

QUESTIONS

LAWRENCE: Is it possible to edit the delivery address during checkout? For example, if I want to order something to be delivered to a friend's house.

KATHY: I saw that there's now a mobile view. Does mobile responsiveness work correctly on all pages?

SAM: We noticed the "Login with Google" button, but we didn't see any functionality tied to it. Does this work?
